

PROJECTION SYSTEM

BACKGROUND OF THE INVENTION

5 This invention relates generally to image projectors, and more particularly, to modifying projected images.

 Portable digital image projectors are common. Such digital image projectors, while connected to a personal computer or other image/video source, sit on a surface and are directed at a projection surface to show a "slide" presentation or a video presentation. Many of these projectors use transmissive or reflective liquid crystal
10 displays, and typically only have a single main lens. Other such projectors use different imaging devices, such as digital micro-mirrors, and may include more than one lens. The projectors can display images one at the time or as a sequence of images, as in the case of video.

15 These digital projectors are typically designed so that undistorted rectangular images are projected on the projection surface when the projector is placed horizontally on a level support surface with the projector's optical axis lined up perpendicular to the projection surface. However, if the alignment and orientation is modified, then the resulting image on the projection surface may be distorted. In many
20 cases the image will appear as a trapezoid, and in other cases an arbitrarily shaped quadrilateral. The non-rectangular shape of the resulting projected image is referred to as keystoneing.

 One technique to adjust for keystoneing is to tediously adjust the physical position of the projector by moving it around, tilting and rotating it, until a near
25 rectangular image is displayed. However, in many situations, it may not be feasible to sufficiently physically adjust the position of the projector. For example, the projector may need to be positioned above or below the display surface for proper image presentation.

5 United States Patent No. 5,548,357, entitled "Keystoning and focus
correction for an overhead projector," describes a system where a test slide is displayed.
A user then identifies line pairs that appear to be parallel to each other. The user
identified line pair activates a distortion correction program that uses the oblique angle
between the horizontal plane through the projector and the viewing screen. This is a
10 burdensome task for a user to correctly perform.

United States Patent No. 5,795,046, entitled "Method for pre-
compensating an asymmetrical picture in a projection system for displaying a picture,"
describe a system where the projection angle, and the trapezoidal error, is compensated
for by the user entering positional information into the system via a keyboard. The
15 determination and inputting of positional information is difficult and burdensome for
the user.

United States Patent Publication 2002/0021418 A1, entitled "Automatic
Keystone Correction For Projectors With Arbitrary Orientation", describes a projection
system that includes a pair of tilt sensors and a camera. The system using data from the
20 tilt sensors and the camera warps the projected image to display an image that is
rectangular. Unfortunately, the tilt sensors tend to be expensive and the system requires
complex re-calibration when the projector lens moves, e.g., when the projector is
zoomed and/or focused. This inherent complexity increases the expense of the resulting
projector.

25

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an existing projection system.
FIG. 2 is a modified projection system.
30 FIG. 3 illustrates a self adjusting projection system.
FIG. 4 illustrates keystone correction with autofocus.
FIG. 5 shows a focused image.
FIG. 6 shows an out of focus image

5 FIG. 7 shows the spectrum of FIG. 6.
 FIG. 8 shows the spectrum of FIG. 5.
 FIG. 9 illustrates image adjustment in accordance with screen size.
 FIG. 10 illustrates image filtering.
 FIG. 11 illustrates a captured image.
10 FIG. 12 shows an interactive keystone adjustment.
 FIG. 13 shows a keypad.
 FIG. 14 illustrates the use of a second imaging source.
 FIG. 15 shows projection roll.
 FIG. 16 shows corrected projection roll.

15

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

 Referring to FIG. 1, a typical projection system includes an enclosure housing the electronics and imaging devices. To set up a projector to display an image properly many steps are performed which typically include, (1) connecting a cable to a laptop or other image source, (2) switching a power switch (on/off), (3) adjusting the vertical angle of projection, (4) focusing the image on the display, (5) adjusting the zoom of the image, and (6) manually adjusting the keystone. As it may be observed, this includes many steps which typically need to be performed in a suitable order.

25 Referring to FIG. 2, a modified projection system includes an enclosure housing the electronics and imaging devices. To set up the modified projector to display an image properly fewer steps are performed which typically include, (1) connecting a cable to a laptop or other image source, (2) switching a power switch (on/off), and (3) selecting the auto-set up function. As it may be observed this requires considerably fewer operations and is less likely to be performed in an improper manner.

30

 Referring to FIG. 3, the primary components of a self-adjusting (setting-free) projector include an imaging sensor system 10, an image pre-processing module 12, projection screen detection module 14, focus detection and auto-focus module 16,

5 keystone detection and correction module 18, image centering and zooming module 20, projector control system 22, and projector optical and mechanical components 24.

The imaging sensor system 10 may contain one or more imaging sensors, or imaging sensor pairs forming a stereo pair. Individual imaging sensors may be one-dimensional or two-dimensional sensors. The imaging sensors may also include the
10 projector optics, such as the projection lens. In the case of a pair of sensors, the relative angular deviation between the surface onto which the image is projected and the image plane of the projector may be used as the basis of image modification, such as keystoneing. It is noted that a vertical tilt sensor may be included, if desired.

The present inventors considered the projector system of United States
15 Patent Publication 2002/0021418 A1, entitled "Automatic Keystone Correction For Projectors With Arbitrary Orientation", described above, and determined that occasionally the projector system will fail to properly keystone compensate. After considering the inability to properly keystone compensate the present inventors came to the realization that such a potential failure is, at least in part, the result of the projector
20 being sufficiently out of focus. In many cases, the user will tend to manually focus the projector prior to keystoneing which will alleviate the concern. However, in other cases the user will consider the projector sufficiently focused for their current needs and will attempt to keystone correct the image without success, thus resulting in frustration to the user. Referring to FIG. 4, to overcome this previously unconsidered limitation, the
25 system preferably auto-focuses prior to keystone correction. While any number of different auto-focus mechanisms may be used, the system preferably uses an appropriate test pattern to determine whether or not the projector is in focus (see FIG. 5). In the event the system is not properly focused (see FIG. 6), an iterative process where the amount of de-focus is determined, the lens is focused, the amount of de-focus is
30 determined, the lens is focused, etc. is undertaken. One technique for determining the amount of de-focus is to use the frequency spectrum of the image of the projected test pattern (see FIG. 7) and compare it with a reference frequency spectrum (see FIG. 8) of the image of the test pattern acquired when the projector is properly focused. Other de-

5 focus (or focus) detection, determination, and adjustment mechanisms may likewise be utilized, as desired. After performing an auto-focus of the projection system, then the system applies a keystone compensation.

10 In one embodiment, the keystone compensation may be manually performed by the user after automatic auto focus. In another embodiment, the keystone compensation may be automatically performed by the system after automatic auto focus. In yet another embodiment, the keystone compensation may be partially manual and partially automatically performed after automatic auto focus. The auto-focus function should be invoked by the system as a result of activating or otherwise performing the keystone compensation. The activation of the auto-focus function, as applied to
15 keystone compensation, should be in a manner free from separate user selection of the otherwise existing auto-focus function of the projector. In this manner, the focus of the system is ensured prior to completion of the keystone correction.

The present inventors further considered the projector system described in R. Sukthankar et al., "Smarter Presentations: Exploiting Homography In Camera-
20 Projector Systems," IEEE ICCV Conference, 2001, described above, and determined that while the use of the single camera can be used to estimate the parameters of the keystone effect, however, there is no guarantee that the projected image after keystone correction maintains the correct aspect ratio. In particular, the system needs to compute C. This is performed by detecting the four screen corners in the image domain, the four
25 physical screen corners, and then solve for C. Unless the physical screen happens to have the same aspect ratio as the screen the system can not obtain the correct aspect ratio. To overcome such a limitation the present inventors determined that interactivity with the user and the projection system can overcome such aspect ratio limitations.

Referring to FIG. 9, the corners of the projection screen may be
30 identified, such as the upper left corner, the upper right corner, the lower left corner, and the lower right corner. With all four corners identified, or at least a pair of diagonal corners identified, the aspect ratio of the projection screen may be determined. Alternatively, the system could detect the edges of the projection screen and from that

5 determine the general boundaries of the projection screen. In any case, the identification
of one or more aspects of the projection screen indicating a region that is suitable for
displaying an image on, or otherwise the exterior boundary of the projection screen, will
be referred to as a boundary. In many cases, the aspect ratio of the projection screen is
similar to the desired aspect ratio of the projected image. In some cases, only the upper
10 or lower corners of the projection screen are detected, in which case, the width of the
projection screen may be used as the basis to predict a typical aspect ratio of the screen,
such as a 4:3 aspect ratio. In a similar manner, the vertical edges of the projection
screen may likewise be used. In some cases, only the right or left corners of the
projection screen are detected, in which case, the height of the projection screen may be
15 used as the basis to predict a typical aspect ratio of the screen, such as a 4:3 aspect ratio.
In a similar manner, the horizontal edges of the projection screen may likewise be used.

The projected image, such as using a test pattern, is sensed by the camera
and compared with the size of the projection screen. This may be done by comparing
the four corners of the projected test pattern with the four corners (or otherwise) of the
20 detected projection screen. Then, adjustments to the projected image may be made to
shift the edges of the projected image in accordance with the projection screen. The
sensing of the projected image by the camera and resizing the projected image may be
repeated until the desired size (horizontal and/or vertical) and/or aspect ratio of the
projected image is achieved. For example, if the projection is to the left of the screen,
25 the screen detection module may sense such an alignment and output a set of control
parameters to cause the projector to shift towards the right-hand side. In one
embodiment, the control parameters may be the distance between the mass centers of
the projection screen and the projected image. The system may use any suitable
relationship between the projected image and the size of the projection screen. For
30 example, the image may be centered on the projection screen and sized to fit
approximately 90% of the projection screen. For example, if the projection is larger
than the detected screen, then the projector may zoom in; and if the projection is smaller
than the detected screen, then the projector may zoom out.

5 Referring to FIG. 10, one technique to detect the projection screen is to
use a one-dimensional imaging sensor. An input data line is median-filtered 80 to
remove noise since a typical inexpensive sensor captures data with significant noise
level. The median filter is preferred due to its property of preserving discontinuity. The
filtered data is then passed into a gradient computation module 82. It is noted that
10 absolute luminance level is not the most reliable cue for identifying a screen, since there
may be luminance variations due to shadows/shades as illustrated in FIG. 11. Thus the
detection is preferably performed in the gradient domain. After the gradients are found,
a zero-crossing/peak locator module 84 locates the zero-crossings and peaks in the
gradient array. The zero-crossing/peaks are presumably the boundaries of the screen.
15 Since typically there are multiple zero-crossings/peaks, and not all of them correspond
to valid screen boundaries, the candidate pair matcher module 86 matches two zero-
crossings/peaks to form a pair that is a plausible candidate of screen. The match is
based on multiple criteria such as width of the screen, average brightness of the screen,
etc. This module will obtain multiple such pairs. A statistical inference module 88 uses
20 an inference algorithm to choose the most plausible pair, based on empirical
probabilities that reflect the importance of each type of the cues used.

 The basic principles of the above approach can be extended to the 2-D
sensor case where the input array is 2-dimensional. In fact, one can even use the above
1-D approach to process the sensed 2-D array row by row, and then column by column.
25 However, a preferred approach will also utilize the additional 2-D constraints such as
that all 1-D screen boundaries in the horizontal direction should form two lines in the
vertical direction. Alternatively, with 2-D data, one can start with edge detection, then
perform line detection, and then extract a quadrilateral that encloses an area of relatively
uniform color (white) and typically relatively brighter than the background. It is noted
30 that the projection screen may be identified with one or more cameras.

 After the detection of the projection screen an interactive technique may
be used to permit the user to further adjust the aspect ratio, and/or keystone, if desired.
These techniques may likewise be used to over-ride the automatic adjustments and also

5 provide proper operation when the range of operation for the automatic methods is
exceeded (e.g., in a very dark room). Such techniques should require minimal user
interaction for ease of use. A “keystone adjustment pattern” is projected which the user
interacts with via the laser pointer (or otherwise a pointing device) that is integrated
with the projector remote control or separate from the projector, or alternatively by
10 selecting the appropriate functions on the projector. The user starts and stops interactive
adjustment on the basis of visual feedback by observing the dynamically changing shape
of the keystone correction pattern in response to user’s actions. In addition, after
detection of the projection screen the system may, if desired, perform auto focus, auto
centering (positioning), auto zooming, and auto keystoneing, all without further user
15 interaction with the projector. Also, after detection of the projection screen the system
may perform auto centering (positioning) and/or auto zooming.

Referring to FIG. 12 a rectangular pattern may be used for interactive
adjustment in the preferred embodiment. The pattern will appear as warped rectangle
100 when the keystone effect is present, and will appear to be perfectly (or substantially)
20 rectangular when the keystone effect is corrected. At each one of its corners, the pattern
has a cluster of 4 arrows, pointing north, south, west, and east directions. In one
possible implementation, the user first enters the keystone adjustment mode by selecting
the corresponding option in an on-screen menu, and then uses the laser pointer to adjust
for keystone: whenever the laser beam falls on an arrow, the projection will be adjusted
25 towards that direction. The camera detects the position of the laser and invokes the
correction mechanism, which may be in the form of digital image pre-processing and/or
optical/ mechanical control of the projector imaging system. The laser pointer may be
integrated into the projector remote control or otherwise be separate.

In the preferred implementation, the user interacts with the arrows using
30 the remote control unit of the projector, in particular using four-directional (pointing at
N, S, W, and E) navigation arrows on a typical remote control, e.g., those on a circular
directional pad. Such an ensemble of four arrows placed on a circular pad that can be
pressed in 4 different directions is depicted in FIG. 13.

5 In this implementation, the user first enters the keystone adjustment
mode by selecting the corresponding option on the on-screen display menu. The
keystone adjustment pattern is then projected. Prior to adjustment, the user first selects
one of the four corners that will be adjusted. There are many possible ways of making
this selection. For example, the user makes a selection by pressing/clicking on a button
10 on the remote control, or on a soft button on the on-screen display (henceforth the
SELECT button). As the user presses the SELECT button, the four-arrow cluster
appears on one particular corner signaling the fact that the corner is selected for
adjustment. The user then selects any one of the four directions by pressing on the four
corresponding directional arrows on the directional pad on the remote control unit (FIG
15 13). After the adjustment is completed, when the user presses/clicks on the SELECT
button, the next corner is selected. This is signaled to the user by the appearance of the
four-arrow cluster at the next selected corner. By pressing the SELECT button
repeatedly, the user can jump from one corner to the next in clockwise fashion. When a
corner is selected, the four-arrow cluster appears on that corner to provide visual
20 confirmation to the user. The remaining three corners do not have the four-arrow
cluster.

 A similar paradigm to the one described above can be used for
interactive aspect ratio adjustment. Two arrows (up and down or left and right) placed
on any appropriate part of the adjustment pattern are used to stretch and squeeze the
25 image to interactively adjust for the correct aspect ratio.

 In many cases there is no projection screen or otherwise a wall with
discernable boundaries that is used to display the image on. In this case, it is problematic
to use a single imaging device in order to provide effective keystone correction.
Accordingly, the system may use two or more imaging devices, such as two or more
30 cameras, or one or more cameras together with the projector's optical system. The pair
of optical sensing devices may be used to estimate the relative horizontal deviation
angle and vertical deviation angle, typically using a projected test pattern, from which
the keystone correction parameters may be estimated.

5 Depth to the projection surface is useful in estimating the relative
projection surface orientation. The relative angles may be computed from the depth of
the test patterns relative to the projector. While the use of a single sensor coupled with
the projector optics is acceptable, it is difficult to obtain an accurate estimate of the
distance from the projector to the display surface. In order to obtain a more accurate
10 estimate of the distance from the projector to the display surface a depth-sensing device
(e.g., a stereo camera), apart from the projector optics, may be used. In order to reduce
expense, the depth sensing device may be a one-dimensional imaging sensor pair, if
desired (such as illustrated in FIG. 14). The depth estimation may likewise be used to
increase the accuracy of the projection screen detection module. Also, the system may
15 place a constraint on the detected corners of the projection screen that they are
co-planar, which is normally the case, in order to make the depth estimation more
robust."

 In another embodiment the imaging may use the projector optics (e.g.,
the projector lens) together with one or more other imaging devices. The imaging
20 devices may be maintained in a fixed location with respect to the projector, and are
preferably integral therewith. However, it has been determined that if the projector
optics are adjusted in some manner during use, then the system needs to be re-calibrated
for a new set of parameters to compensate for the zooming and/or focusing and/or lens
shifting. To overcome this limitation, the prevent inventors determined that the system
25 may pre-calibrate the optics of the projector so that the new parameters of the projector
optics can be computed from the lens control parameters, as the lens is moved during
zooming and/or focusing and/or lens shifting. The pre-calibration may include
modeling the variations in the optical parameters as a function of one or more of the
lens control parameters, so that the on-line re-calibration can be done automatically.
30 The calibration may include calculations from pre-calibrations or otherwise a look-up
table.

 Referring to FIG. 15, after keystone correction the projected image may
be rectangular but it is not necessarily properly oriented with respect to the user, which

5 typically desires the top and bottom edges to be horizontal, and the right and left edges to be vertical. In some embodiments the detected projection screen, or parts thereof, may be used as a basis to correct for projection roll so that the projector will be aligned with the real world, as illustrated in FIG. 16.
